

# Chapter 4

## Network Layer

---

A S M Touhidul Hasan, Ph.D.  
Assistant Professor,  
Department of CSE, UAP

# Chapter 4: Outline of Lecture 17

## 4.7 broadcast and multicast routing

# Broadcast routing

- ❖ deliver packets from source to all other nodes
- ❖ source duplication is inefficient:

- ❖ source duplication: how does source determine recipient addresses?

# In-network duplication

- ❖ *flooding*: when node receives broadcast packet, sends copy to all neighbors
  - problems: cycles & broadcast storm
- ❖ *controlled flooding*: node only broadcasts pkt if it hasn't broadcast same packet before
  - node keeps track of packet ids already broadcasted
  - or reverse path forwarding (RPF): only forward packet if it arrived on shortest path between node and source
- ❖ *spanning tree*:
  - no redundant packets received by any node

# Spanning tree

- ❖ first construct a spanning tree
- ❖ nodes then forward/make copies only along spanning tree

(a) broadcast initiated at A

(b) broadcast initiated at D

# Spanning tree: creation

- ❖ center node
- ❖ each node sends unicast join message to center node
  - message forwarded until it arrives at a node already belonging to spanning tree

(a) stepwise construction of spanning tree (center: E)

(b) constructed spanning tree

# Multicast routing: problem statement

**goal:** find a tree (or trees) connecting routers having local mcast group members

- ❖ **tree:** not all paths between routers used
- ❖ **shared-tree:** same tree used by all group members
- ❖ **source-based:** different tree from each sender to rcvrs

legend

group member

not group member

router with a group member

router without group member

shared tree

source-based trees

# Approaches for building mcast trees

approaches:

- ❖ *source-based tree*: one tree per source
  - shortest path trees
  - reverse path forwarding
- ❖ *group-shared tree*: group uses one tree
  - minimal spanning (Steiner)
  - center-based trees

...we first look at basic approaches, then specific protocols adopting these approaches

# Shortest path tree

- ❖ mcast forwarding tree: tree of shortest path routes from source to all receivers
  - Dijkstra's algorithm

## LEGEND

router with attached group member

router with no attached group member

link used for forwarding, i indicates order link added by algorithm

# Reverse path forwarding

- ❖ rely on router's knowledge of unicast shortest path from it to sender
- ❖ each router has simple forwarding behavior:

***if*** (mcast datagram received on incoming link on shortest path back to center)  
***then*** flood datagram onto all outgoing links  
***else*** ignore datagram

# Reverse path forwarding: example

## LEGEND

-  router with attached group member
-  router with no attached group member
-  datagram will be forwarded
-  datagram will not be forwarded

- ❖ result is a source-specific *reverse* SPT
  - may be a bad choice with asymmetric links

# Reverse path forwarding: pruning

- ❖ forwarding tree contains subtrees with no mcast group members
  - no need to forward datagrams down subtree
  - “prune” msgs sent upstream by router with no downstream group members

# Shared-tree: steiner tree

- ❖ *steiner tree*: minimum cost tree connecting all routers with attached group members
- ❖ problem is NP-complete
- ❖ excellent heuristics exists
- ❖ not used in practice:
  - computational complexity
  - information about entire network needed
  - monolithic: rerun whenever a router needs to join/leave

# Center-based trees

- ❖ single delivery tree shared by all
- ❖ one router identified as “*center*” of tree
- ❖ to join:
  - edge router sends unicast *join-msg* addressed to center router
  - *join-msg* “processed” by intermediate routers and forwarded towards center
  - *join-msg* either hits existing tree branch for this center, or arrives at center
  - path taken by *join-msg* becomes new branch of tree for this router

# Center-based trees: example

suppose R6 chosen as center:

## LEGEND

-  router with attached group member
-  router with no attached group member
-  path order in which join messages generated

# Internet Multicasting Routing: DVMRP

- ❖ **DVMRP**: distance vector multicast routing protocol, RFC1075
- ❖ *flood and prune*: reverse path forwarding, source-based tree
  - RPF tree based on DVMRP's own routing tables constructed by communicating DVMRP routers
  - no assumptions about underlying unicast
  - initial datagram to mcast group flooded everywhere via RPF
  - routers not wanting group: send upstream prune msgs

# DVMRP: continued...

- ❖ *soft state*: DVMRP router periodically (1 min.) “forgets” branches are pruned:
  - mcast data again flows down unpruned branch
  - downstream router: re prune or else continue to receive data
- ❖ routers can quickly regraft to tree
  - following IGMP join at leaf
- ❖ odds and ends
  - commonly implemented in commercial router

# Tunneling

**Q:** how to connect “islands” of multicast routers in a “sea” of unicast routers?

physical topology

logical topology

- ❖ mcast datagram encapsulated inside “normal” (non-multicast-addressed) datagram
- ❖ normal IP datagram sent thru “tunnel” via regular IP unicast to receiving mcast router (recall IPv6 inside IPv4 tunneling)
- ❖ receiving mcast router unencapsulates to get mcast datagram

# PIM: Protocol Independent Multicast

- ❖ not dependent on any specific underlying unicast routing algorithm (works with all)
- ❖ two different multicast distribution scenarios :

## *dense:*

- ❖ group members densely packed, in “close” proximity.
- ❖ bandwidth more plentiful

## *sparse:*

- ❖ # networks with group members small wrt # interconnected networks
- ❖ group members “widely dispersed”
- ❖ bandwidth not plentiful

# Consequences of sparse-dense dichotomy:

## *dense*

- ❖ group membership by routers *assumed* until routers explicitly prune
- ❖ *data-driven* construction on mcast tree (e.g., RPF)
- ❖ bandwidth and non-group-router processing *profligate*

## *sparse:*

- ❖ no membership until routers explicitly join
- ❖ *receiver-driven* construction of mcast tree (e.g., center-based)
- ❖ bandwidth and non-group-router processing *conservative*

# PIM- dense mode

**flood-and-prune RPF:** similar to DVMRP but...

- ❖ underlying unicast protocol provides RPF info for incoming datagram
- ❖ less complicated (less efficient) downstream flood than DVMRP reduces reliance on underlying routing algorithm
- ❖ has protocol mechanism for router to detect it is a leaf-node router

# PIM - sparse mode

- ❖ center-based approach
- ❖ router sends *join* msg to rendezvous point (RP)
  - intermediate routers update state and forward *join*
- ❖ after joining via RP, router can switch to source-specific tree
  - increased performance: less concentration, shorter paths

# PIM - sparse mode

## *sender(s):*

- ❖ unicast data to RP, which distributes down RP-rooted tree
- ❖ RP can extend mcast tree upstream to source
- ❖ RP can send *stop* msg if no attached receivers
  - “no one is listening!”

# Chapter 4: *done!*

## 4.1 introduction

## 4.2 virtual circuit and datagram networks

## 4.3 what's inside a router

## 4.4 IP: Internet Protocol

- datagram format, IPv4 addressing, ICMP, IPv6

## 4.5 routing algorithms

- link state, distance vector, hierarchical routing

## 4.6 routing in the Internet

- RIP, OSPF, BGP

## 4.7 broadcast and multicast routing

- ❖ understand principles behind network layer services:
  - network layer service models, forwarding versus routing how a router works, routing (path selection), broadcast, multicast
- ❖ instantiation, implementation in the Internet
